BIOREACTOR AS REMEDIATION SYSTEM

A bioreactor is a biotechnological device capable of producing a controlled and isolated environment that guarantees and maximizes the growth of a culture of microorganisms that carry out the degradation of the

contaminants of interest in the aquifer

BIOREACTOR DEVELOPMENT: WORKFLOW

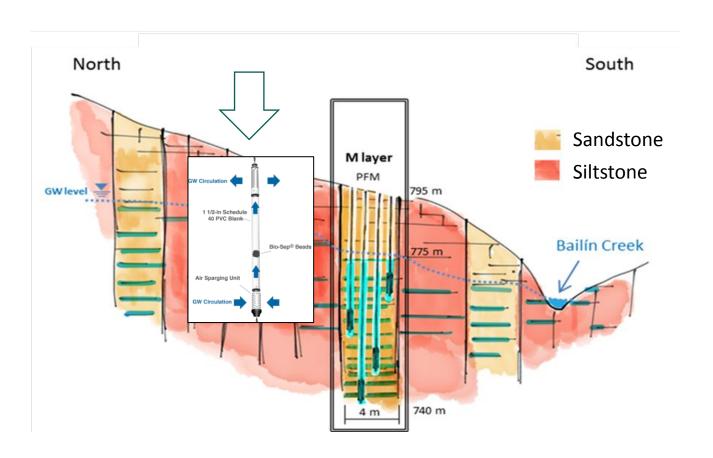

LOCATION

BIOREACTOR CONFIGURATION

¿Why an in-situ bioreactor?

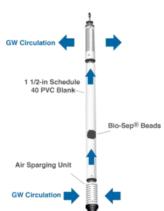

- Fractured bedrock, impact in groundwater
- Areas with ↓ contaminant concentrations
- Low hidraulic connectivity of siltstone layers
- More stable environment

STEP 2: ADDITIONAL CHARACTERIZATION OF INOCULUM CANDIDATES

Samples selected for biostimulation experiments

Samples selected to be used as co-inoculants

STEP 3: BIOSTIMULATION AND BIOAUGMENTATION EXPERIMENTS

CONCLUSIONS

Implementation of a bioreactor as remediation system is not a straightforward process that requires a deep understanding of the medium and factors affecting bioreactor performance

The design of a bioreactor accounts for a sequential scaling process where parameters may be carefully optimized and controlled to ensure a proper system efficiency

The development of an efficient bioreactor is a long-term process where microbial communities may be gradually adapted to environmental site conditions in order to ensure microbial growth and improve rates of biodegradation

Interesting samples have been found in the Bailin aquifer to continue with the scaling process for the potential implementation of a field bioreactor
